## GROWER SUMMARY

## Headline

- Depending on the season and the crop load, fruit thinning may not always lead to increased returns in apple orchards.

## Background and expected deliverables

Tree fruit growers are keen to develop chemical and/or mechanical methods of fruit thinning to reduce reliance upon expensive hand thinning operations. Indeed the HDC Tree Fruit Panel considers this to be a high priority in its research strategy.

Apple trees often set excessive numbers of fruit in relation to tree size resulting in the production of large numbers of small fruit. Thinning or removing a proportion of these fruit enables the remaining fruit to reach a larger size, and these are easier and cheaper to pick. This enables growers to produce fruit in the desired size range for market requirements. In addition to increasing fruit size, thinning can also be carried out to increase fruit quality, for instance, when damaged fruit is removed from the tree. Thinning is also carried out to prevent over cropping, as in some varieties this can lead to biennial bearing.

There have been recent developments in both chemical and mechanical fruit thinning techniques. If effective, such developments could reduce or remove the cost of the hand thinning operation. This project investigated such alternative thinning techniques for Gala apple.

## Summary of the project and main conclusions

The treatments applied in 2011 were as follows:

## 1. Untreated

2. Hand thinning at $12-15 \mathrm{~mm}$ according to agronomists' recommendations
3. Exilis applied at $8-12 \mathrm{~mm}$ fruit size at $7.5 \mathrm{I} / \mathrm{ha}$ in a water volume of $500 \mathrm{I} / \mathrm{ha}$, when temperature is forecasted to be above $15^{\circ} \mathrm{C}$ for the two days following application
4. Ammonium thiosulphate (ATS) applied at open flower at a rate of $2 \%$ applied as 500 I/ha
5. ATS applied at open flower at a rate of $2 \%$ applied as $500 \mathrm{I} /$ ha + Exilis applied at $8-12$ mm fruit size at $7.5 \mathrm{I} / \mathrm{ha}$, when temperature is forecasted to be above $15^{\circ} \mathrm{C}$ for the two
days following application, in a water volume of $500 \mathrm{I} / \mathrm{ha}$
6. Cerone ( $0.75 \mathrm{l} / \mathrm{ha}$ in a water volume of $500 \mathrm{l} / \mathrm{ha}$ ) applied at petal fall
7. Cerone ( $0.75 \mathrm{I} / \mathrm{ha}$ in a water volume of $500 \mathrm{I} / \mathrm{ha}$ ) applied at petal fall + Exilis applied at $8-12 \mathrm{~mm}$ fruit size at $7.5 \mathrm{I} / \mathrm{ha}$, when temperature is forecasted to be above $15^{\circ} \mathrm{C}$ for the two days following application, in a water volume of $500 \mathrm{I} / \mathrm{ha}$
8. Mechanical blossom thinning using the Fruit-Tec Darwin thinner

The treatments applied in 2012 were as follows:

1. Untreated
2. Hand thinning to doubles per cluster at $12-15 \mathrm{~mm}$
3. Hand thin all small, under-developed fruit per cluster at $12-15 \mathrm{~mm}$
4. Exilis applied at $8-12 \mathrm{~mm}$ fruit size at $7.0 \mathrm{l} / \mathrm{ha}$, in a water volume of $1000 \mathrm{l} /$ ha with $0.5 \%$ $\mathrm{Li}-700$, when temperature was forecasted to be above $15^{\circ} \mathrm{C}$ for the two days following application
5. Exilis applied at $8-12 \mathrm{~mm}$ fruit size at $7.0 \mathrm{I} / \mathrm{ha}$, with $0.175 \mathrm{I} / \mathrm{ha}$ Tipoff and $0.5 \% \mathrm{Li}-700$, when temperature was forecasted to be above $15^{\circ} \mathrm{C}$ for the two days following application, in a water volume of $1000 \mathrm{l} / \mathrm{ha}$

Treatments applied in 2011 at bloom were ineffective at reducing crop load; however reports from growers suggest that ATS (ammonium thiosulphate) and the Darwin mechanical blossom thinner are feasible alternatives to hand thinning.

Post-blossom alternatives, such as Exilis (6-benzyladenine), to hand thinning, have been shown to be effective at reducing crop load. Exilis reduced crop load by $48 \%$ in 2011 and $19 \%$ in 2012, the difference between years being attributable to cooler temperatures immediately post application in 2012. It has also been shown that hand thinning can have little effect on fruit number at harvest if the level of thinning is insufficient for the crop load on the tree. In 2012, fruit was thinned to two fruit per cluster and this had no significant effect on fruit numbers at harvest, whereas in 2011 fruit was thinned to a single fruit per cluster and here the fruit number at harvest was significantly reduced.

In 2011 a greater thinning effect was observed than in 2012, and in 2011 it was shown that by reducing crop load, fruit size increased. There were greater returns for fruit in the larger size classes, but the reduction in fruit number outweighed this increase in return per apple, resulting in a reduction in income per tree.

In 2012 there were no significant differences between the treatments and the un-thinned control for return per tree. However there was a difference between hand thinning all small fruit and the Exilis application, with a greater return achieved from the Exilis application. The Exilis application gave a greater proportion of larger fruit than the 'hand thinning small fruit' treatment, where a greater price was achieved for the larger fruit. In addition to this, the thinning cost for the Exilis application was less per tree than the cost of hand thinning the small fruit.

Applications of Exilis in 2011 showed no adverse effects on return bloom compared to the control.

Before drawing any major conclusions from this trial, it should be remembered that it was only carried out over a two-year period and that in the second year of the project, fruit set was poor due to the wet spring conditions.

## Conclusions from this work

1. Alternatives to conventional hand thinning exist.
2. Thinning clusters to two fruit may not reduce the number of fruit at harvest compared to an un-thinned crop.*
3. Thinning a crop may not result in the greatest potential profit.**
4. Careful consideration is required when making decisions on thinning.
*This was for data from a year where there was a very poor fruit set due to wet weather conditions in spring.
** Thinning may have benefits on preventing biennial cropping and increasing brix levels.

## Financial benefits

Reducing crop load and increasing fruit size may not necessarily lead to an increased return. In 2011 the lowest return per tree was achieved from the greatest thinning effect, ATS + Exilis ( $£ 12.33$ ), whereas the un-thinned treatment returned $£ 18.68$ per tree. This is of course information for one year from one orchard. In 2012 there was no significant effect on financial return for any of the treatments compared to the control.

In 2012, hand thinning fruit to doubles per cluster did not significantly reduce fruit number compared to the control, nor was there a significant change in return per tree. However, the effect of carrying out this exercise would be to spend more money producing the crop which, although it would be recouped on the sale of the crop, would have an impact on cash flow during the growing season.

## Action points for growers

- Decisions on the level of thinning required need to be based on initial crop load, and potential return for each size class.
- If the prices are known for each size class, an informed decision can be made on the level of thinning required.
- If thinning is required to increase crop size, Exilis can be used as an alternative to hand thinning.

## SCIENCE SECTION

## Introduction

Effective fruit thinning and increasing fruit size through the use of chemicals or mechanical methods, whilst reducing or removing the cost of hand-thinning, is seen as a high research priority. In 2012, this project made use of 6-benzyladenine, 1-napthylacetic acid and hand thinning to develop commercially appropriate methods of thinning that potentially have an overall cost benefit to the crop. The aim of the project was to determine the effectiveness and cost benefit of a range of thinning strategies for cv . Gala apple. The specific objectives were:

1. To apply five treatments including an un-thinned control
2. To determine the time taken and cost for each treatment method
3. To determine yield in each size category at harvest for each treatment
4. To determine the cost benefit of each treatment

## Materials and methods

The trial was conducted on Gala apple in Plot number EE191 at East Malling Research, East Malling, Kent. This is a 1.25 ha plot of alternate rows of Mondial Gala and Queen Cox, both on M9 planted in 1999. The trial was laid out in a statistically randomized block design, approved by the EMR biometrician, data was analysed by Anova, Genstat. Weather data was collected during the trial from an on-site weather station.

The treatments applied were as follows:

1. Untreated
2. Hand thinning to doubles per cluster at $12-15 \mathrm{~mm}$
3. Hand thinning of all small fruit per cluster at $12-15 \mathrm{~mm}$
4. Exilis (6-benzyladenine) applied at $8-12 \mathrm{~mm}$ fruit size at $7.0 \mathrm{I} /$ ha with $0.5 \% \mathrm{Li}-700$ (blend of methylacetic acid, processed lecithin - surfactant/wetter/spreader) when temperature was forecasted to be above $15^{\circ} \mathrm{C}$ for the two days following application in a water volume of $1000 \mathrm{I} / \mathrm{ha}$
5. Exilis applied at $8-12 \mathrm{~mm}$ fruit size at $7.0 \mathrm{I} /$ ha with $0.175 \mathrm{I} /$ ha Tipoff (1-naphthylacetic acid) and $0.5 \% \mathrm{Li}-700$ when temperature was forecasted to be above $15^{\circ} \mathrm{C}$ for the two

Hand thinning was carried out on 06/06/12 when the fruit was between 12 and 15 mm diameter. Treatment 2 consisted of thinning fruit in the cluster down to two good fruit. This was achieved by initially removing small, under developed fruit followed by the king fruit and finally removing developing fruit until just two fruit per cluster were left. Treatment 3 was applied by the removal of all small under developed fruit which left all developing fruit in the cluster. Chemical treatments 4 and 5 were applied on 29/05/12 when the fruit was between 8 and 12 mm fruit size and the weather was predicted to be above $15^{\circ} \mathrm{C}$ for the two days following application.

At pink bud flower clusters per tree were assessed and fruit number was determined prior to and post June-drop. At harvest, fruit number and weight was determined for each size class for each tree.

Costs of chemicals used, time taken for application, time taken for hand thinning operations and for harvest were determined for each plot, along with commercially achieved price per fruit category, to enable a simple cost benefit to be determined for each thinning strategy.

This calculation consisted of income minus costs. Income was calculated on yield of each size class multiplied by return to the grower for each size class. For the purposes of this experiment, 2012 prices for fruit were as follows:

- $70 \mathrm{p} / \mathrm{kg}$ for $<60 \mathrm{~mm}$ fruit
- $80 \mathrm{p} / \mathrm{kg}$ for $60-70 \mathrm{~mm}$ fruit
- $84 \mathrm{p} / \mathrm{kg}$ for $>70 \mathrm{~mm}$ fruit.

Net costs were calculated as cost of the thinning operation plus cost of harvest labour (time taken). The hourly rates used in the calculation were $£ 6.84$ / hour for casual staff thinning and picking and $£ 32.00$ / hour for a spray operator with tractor.

## Results

## Fruit number and weight per tree and mean fruit weight

Treatments 3, 4 and 5 showed a significant reduction in mean total fruit number per tree compared to the un-thinned control. However, for total fruit weight no individual treatment
showed a significant difference from the untreated control. Mean fruit weight increased in treatments 2 and 4 compared to the untreated control (treatment 1). Results are shown in Table 1.

Table 1. Mean total fruit number per tree, mean total fruit weight per tree and mean individual fruit weight

| Treatment | Total fruit number | Total fruit weight <br> $\mathbf{( k g )}$ | Mean fruit weight <br> $\mathbf{( g )}$ |
| :--- | :---: | :---: | :---: |

|  | LSD | 5.900 | 5.031 |

## Fruit size distribution

All treatments show a significant reduction in the number of small (<60mm) fruit compared to the control. However, for fruit in the $60-70 \mathrm{~mm}$ range no individual treatment showed a significant difference in fruit number from the untreated control. No individual treatment showed a significant difference from the untreated control in the number of fruit $>70 \mathrm{~mm}$. Results are shown in Table 2.

Table 2. Fruit number per tree by size class

|  | LSD | 46.41 | 40.5 |

## Fruit weight per tree by class

Treatments 3, 4 and 5 showed a significant reduction in weight for fruit less than 60 mm compared to the control. However, no individual treatment showed a significant difference
in fruit weight from the untreated control for the size range $60-70 \mathrm{~mm}$. Treatment 4 showed an increase in in fruit weight for fruit >70mm compared to the control. Results are shown in Table 3.

Table 3. Weight of fruit per tree by size class

## Discussion

The data presented here is for the second year of a two-year project. The Gala trees used cropped well for that orchard, but initial crop load was estimated to be less than that of many commercial orchards. Three treatments resulted in a significantly reduced mean number of fruit per tree compared to the un-thinned trees which had an average final yield of 391.8 fruit per tree. Hand thinning all undeveloped small fruit reduced fruit number by $22.5 \%$ and the application of Exilis reduced fruit number by $19.3 \%$ compared to the unthinned control. Although three treatments resulted in significantly reduced fruit number per tree, no individual treatment resulted in significant differences in total fruit weight per tree
compared to the control. Mean individual fruit weight increased by $13.7 \%$ in the hand thinning to doubles treatment and $21.6 \%$ in the Exilis treatment compared to the control.

In each case except for the Exilis treatment, the number of fruit in the <60mm category exceeded the number of fruit in the $60-70 \mathrm{~mm}$ category. Whereas only in the control was total fruit weight in the $<60 \mathrm{~mm}$ category greater than in the $60-70 \mathrm{~mm}$ category, with the reverse being the case for all other treatments.

There were no significant differences between the treatments and the un-thinned control for return per tree, however there was a difference between hand thinning all small fruit and the Exilis application, with a greater return achieved from the Exilis application. Both treatments significantly reduced the number of fruit per tree compared to the control but the Exilis application gave a greater proportion of fruit in the $60-70 \mathrm{~mm}$ size category than the $<60 \mathrm{~mm}$ category compared to the hand thinning small fruit treatment. A greater price was achieved for fruit in the $60-70 \mathrm{~mm}$ size class than for the $<60 \mathrm{~mm}$ fruit. In addition to this the thinning cost of the Exilis application was less per tree than the cost of hand thinning the small fruit.

Thinning is, however, also used as a method to even out the crop from year to year, reducing peaks and troughs in crop load, which if left can lead to biennial bearing. Gala is a variety that is not particularly prone to biennial bearing and the project was over too short a time period for this to be investigated during the course of the project.

Thinning is also carried out to remove substandard and damaged fruit. Hand thinning provides an opportunity to do this whereas mechanical and chemical methods are either non-selective or too early (at full bloom) to remove substandard fruit.

Although not assessed in this trial, crop load can have an effect on sugar levels within fruit, which has been found to be linked to the number of leaves around a fruit cluster and the number of fruit within the cluster, as well as fruit position on the tree and light interception. This must also be borne in mind when deciding to thin as minimum brix levels are specified by the supermarkets.

## Conclusions

Exilis has been shown to be an effective thinning agent when weather conditions are correct. In 2011 the application of Exilis reduced the number of fruit by $48 \%$ and in 2012 the crop was thinned by $19 \%$, day time temperatures were similar post application in both years
but in 2012 night time temperatures were cooler, resulting in less of a thinning effect. Applications of Exilis in 2011 had no detrimental effect on return bloom.

In 2012 hand thinning all small fruit was also shown to be an effective method of reducing fruit number, as was hand thinning to single fruit in 2011. Hand thinning to two fruit per flower bud cluster in 2012 did not significantly affect the crop load at harvest.

Hand thinning fruit to doubles per cluster did not significantly reduce fruit number compared to the control, nor was there a significant change in return per tree. The effect of carrying out this exercise would be to spend more money producing the crop, which although this could be recouped on the sale of the crop, would have an impact on cash flow during the growing season.

It has been seen that reducing crop load and increasing fruit size may not lead to an increased return as a smaller number of large fruit may generate a greater income than a larger number of small fruit.

Decisions on the level of thinning required need to be based on initial crop load, and potential return for each size class. If the prices are known for each size class an informed decision can be made on the level of thinning required, which if weather conditions are correct, can be effectively achieved by chemical methods.

Care must be taken when extrapolating the data to other varieties as other varieties may well behave quite differently to Gala. In addition this project was only conducted over two years, with differing treatments in each of the years, and in the second year of the project, pollination was extremely poor due to the unusually wet spring weather conditions.
