# Trial Summary

## Introduction

While UK courgette growers have benefitted from recent herbicide approvals, there are still very few crop protection products authorised for this crop. Courgettes are a very minor crop in the UK (924 ha in 2018) and sensitive to many herbicides, including those currently approved.

The majority of growers use plastic mulch to control weeds within the crop, but still struggle with inter-row weed competition. It is common practice to apply authorised herbicides via hooded tractor-mounted spray applicators, shielding the crop foliage while treating the weeds between the rows. Wing-P was authorised under EAMU 0619/18 in 2018 and has improved weed control but later applications are needed to give longevity of control through the crops' life. While diquat was approved for inter-row application to control emerged weeds later after planting, it has now been revoked with a final use up of February 2020, therefore alternatives are required.

The limited range of herbicides leaves gaps in the weed spectrum, and growers experience problems with a wide range of weeds. In particular, polygonum weeds, black nightshade, black bindweed, sow thistle, and a number of grass weeds including annual meadow grass, volunteer cereals (especially barley), wild oat, black-grass and brome are problematic for growers. As well as competing with the crop for nutrients and water, these weeds also hinder pickers reducing harvest efficiency.

The trials covered in this report aimed to screen herbicides for crop safety and efficacy, to increase the weed control options available to courgette growers. The trials tested products that showed promise in earlier work, as well as some completely new treatments. Trials were carried out on both planted and drilled crops, under typical commercial growing conditions to ensure relevant results.

## Method

### Site 1 (transplanted):

Trials were sited at a commercial courgette grower in West Sussex. The trial field was planted on 18<sup>th</sup> June 2018, with courgette variety 'Kronos'.

Trial 1 (over-row): Treatments were applied at four timings – 24 hours post-planting (25/06/2018), five days post-planting (29/06/2018), two weeks post-planting (09/07/2018), and four weeks after planting (24/07/2018). All were applied with a 1.5 m boom, using an Oxford Precision Sprayer knapsack at 200 L/ha water volume. A randomised block design was used with three replicates of twelve treatments, including two untreated controls and a grower standard treatment (isoxaben + clomazone). There were thirty-six plots in total, each 1.65 m x 7 m.

Trial 2 (inter-row): Treatments were applied at three timings – soon after planting (25/06/2018), two weeks post-planting (09/07/2018), and four weeks post-planting (24/07/2018). All were applied with a lance (0.5 m fan width), using an Oxford Precision Sprayer knapsack at 200 L/ha water volume. A randomised block design was used with three replicates of twelve treatments, including an untreated control and a grower standard treatment (diquat). There were thirty-six plots in total, each 3.3 m x 4 m.

Trial 3 (benfluralin): treatments were applied at two timings – pre-power harrowing and plastic laying (08/06/2018) for benfluralin, and post-planting (25/06/2018) for all other herbicides. Treatments were applied either with a 1.5 m boom, or a lance (0.5 m fan width), as appropriate. An Oxford Precision Sprayer knapsack was used, at 200 L/ha water volume. A randomised block design was used with three replicates of six treatments. There were eighteen plots in total, each 3.3 m x 4 m.

### Site 2 (drilled):

Trials were sited at a commercial courgette grower in Gloucestershire. The trial field was drilled on 29<sup>th</sup> May 2018, with courgette variety 'Tosca'.

**Trial 4 (over-row):** Treatments were applied at three timings – pre-emergence, post-drilling (01/06/2018); post-emergence, at approx. three true leaves (29/06/2018); and post-emergence, four weeks post-drilling (11/07/2018). All were applied with a 1.5 m boom, using an Oxford Precision Sprayer knapsack at 200 L/ha water volume. A randomised block design was used with three replicates of twenty-two treatments, including two untreated controls and two grower standard treatments (isoxaben + clomazone OR propyzamide). There were sixty-six plots in total, each 1.85 m x 6 m.

**Trial 5 (inter-row):** Treatments were applied at three timings – pre-emergence, post-drilling (01/06/2018); post-emergence, at approx. three true leaves (29/06/2018); and post-emergence, four weeks post-drilling (11/07/2018). All were applied with a 1.5 m boom, using an Oxford Precision Sprayer knapsack at 200 L/ha water volume. A randomised block design was used with three replicates of twelve treatments. There were thirty-six plots in total, each 1.85 m x 6 m.

All trials were assessed on three occasions, focussing on weed ground cover or percentage of weed killed (efficacy) and crop phytotoxicity (crop safety).

## Results

### Phytotoxicity (crop safety)

#### **Trial 1 (over-row)**

With the exception of Flexidor + Gamit 36 CS applied the day after planting, all treatments applied within a week of planting had a significant effect on the crop which persisted for up to a month after planting (Table 1). This was exhibited mainly as a check to growth with the crop remaining smaller than the untreated controls, or as scorch where Flexidor + Gamit 36 CS was applied over the crop at five days after planting. AHDB 9918 caused scorch and stunting when applied five days after planting, but only stunting when applied a day after planting.

At seven weeks after planting, plots where treatments were applied the day after planting, and AHDB 9987 at half rate in a tank mix with Gamit 36 CS applied at the later timing had recovered to a near acceptable level, or an acceptable level of damage.

All treatments had slightly less effect on the crop when the herbicides were applied the day after planting compared to when they were applied at five days after planting. All give a check to growth, which should be considered with scheduling and speed of growth at application.

AHDB 9985 was tested at two later application timings and had very little effect on the courgette plants when applied at four weeks after planting, compared to when it was applied two weeks later at flowering. But, even when AHDB 9985 was applied at flowering the effect on the crop was a stunt which was recorded as only just under the acceptable score. In Trial 5 a bleaching was observed, which was likely due to weather conditions at application – which was dull, and therefore the courgette leaves may not have been ‘waxed up’.

**Table 1.** Mean phytotoxicity scores at three dates throughout the Trial 1 assessment period (0 to 10; 0 = complete crop death, 10 = no damage). Scores ≥8 deemed commercially acceptable damage, those <8 (unacceptable damage) are highlighted in bold. Letters denote spray timing: B = 1 day after planting, C = 5 days after planting, D = 4 weeks after planting, E = flowering.

\* Statistically different to untreated

### **Trial 2 (inter-row)**

A number of the treatments caused a check to speed of growth even when applied inter-row, but in many cases it was only just under an acceptable score with no crop loss (Table 2). At the end of the assessment period (early fruit) those treatments which did not have a score below eight were; the commercial standard diquat, AHDB 9995 in a tank mix with Flexidor and Gamit 36 CS, AHDB 9998, AHDB 9825 (alone and in a tank mix with Wing-P), and AHDB 9897 + Phase II.

Crop effects seen were a check to speed of growth and crop variability, and a little transient scorch or yellowing from the contact desiccants Shark, AHDB 9897 and Finalsan. The check to growth would likely be acceptable if enough weed control is gained as this can be factored into schedules, for example this approach is used where Wing-P is now included in commercial programmes.

**Table 2.** Mean phytotoxicity scores at three dates throughout the Trial 2 assessment period (0 to 10; 0 = complete crop death, 10 = no damage). Scores  $\geq 8$  deemed commercially acceptable damage, those  $< 8$  (unacceptable damage) are highlighted in bold. Letters denote spray timing: B = 1 day after planting, D = 4 weeks after planting, E = flowering.

| Treatment                                    | Timing | Mean crop damage scores |                       |                         |

\* Statistically different to untreated

### Trial 3 (benfluralin)

There were no significant differences between scores, but where any herbicides were applied over the crop post-planting, this caused the crop damage score to drop below an acceptable level by causing a check to crop growth which set the crop back a week. However, by the final assessment at early fruiting all plots treated with all except AHDB 9918 had recovered to a near acceptable standard (Table 3). Bonalan (benfluralin) did not cause any unacceptable damage to the courgettes, or any perceptible reduction in the speed of growth.

**Table 3.** Mean phytotoxicity scores at three dates throughout the Trial 3 assessment period (0 to 10; 0 = complete crop death, 10 = no damage). Scores  $\geq 8$  deemed commercially acceptable damage, those  $< 8$  (unacceptable damage) are highlighted in bold. Letters denote spray timing: A = pre-planting and incorporated, and B = 5 days after planting.

| Treatment                             | Timing | Mean crop damage scores                       |  |  |

\* inter-row application

#### **Trial 4 (over-row)**

All of the pre-emergence herbicide treatments were safe to use in drilled courgettes in this trial with only a little yellowing caused where AHDB 9987 + Gamit was applied (Table 4). This occurred at two months after application and would be likely to be caused by the Gamit moving into the rooting zone after a rain event. However, the damage was only just under acceptable. Wing-P 2.0 L/ha was damaging and caused crop death in the drilled pumpkin trial (see separate report SP13. 2018) so care still needs to be taken when using this product in a drilled cucurbit crop. The soil type at this trial site was a clay loam, and demonstrates the influence that soil type can have on crop safety with the product being safe at this site, but causing crop death on the pumpkin trial site with a sandy soil. However, at this site it still caused a slight but acceptable check to the speed of growth of the courgettes.

None of the post-emergence applications caused any unacceptable crop effects with the exception of AHDB 9994, which caused a moderate check to the growth of the crop, scorch and yellow spotting. In the inter-row application of diquat there was drift which caused crop death and confounded assessment of the effects of AHDB 9985, although yellowing was observed after application of AHDB 9985 when applied at flowering. This was not seen at the Trial 1 site, but conditions at application at Trial 4 were duller and therefore there would be more risk of damage if the leaves were not as well waxed up at application.

**Table 4.** Mean phytotoxicity scores at three dates throughout the Trial 4 assessment period (0 to 10; 0 = complete crop death, 10 = no damage). Scores  $\geq 8$  deemed commercially acceptable damage, those  $< 8$  (unacceptable damage) are highlighted in **bold**.

### Weed cover

#### ***Trials 1-3***

There were no significant differences in weed reduction in these trials as weed levels were low. Results of the percentage reduction in weed levels compared to the untreated are shown in Tables 6, 7 and 8.

#### ***Trial 1 (over-row)***

**Table 6.** Percentage reduction in weed cover at Trial 1 (calculated using Abbott's formula) – values highlighted in red show an increase in weed cover. Letters denote spray timing: B = 1 day after planting, C = 5 days after planting, D = 4 weeks after planting, E = flowering.

| Treatment                     | Timing | Weed cover reduction (%) |                       |
|-------------------------------|--------|--------------------------|-----------------------|

\*Untreated control; treatments 1 and 2

### **Trial 5 (inter-row)**

Five products gave equivalent or better reduction in the percentage weed cover when compared to the standard inter-row application of diquat (Table 10). The treatments were Wing-P at either 2.0 or 4.0 L/ha, AHDB 9897 + Phase II, Shark and Finalsan + Activator 90 applied twice.

AHDB 9897 + Phase II was the most effective treatment reducing the weed level by the highest percentage. Finalsan + Activator 90 was much more effective as a double application when compared to the single application, increasing weed reduction from 35% to 71.7%.

**Table 10.** Mean percentage weed kill by visual estimation (weed reduction) values for Trial 5 For example, 100%= 100% weeds killed with zero weeds present. Letters denote spray timing: F = pre-emergence, G = at 3 true leaves, H = one month after drilling (flowering)

| Treatment                                   | Timing | Mean % weeds reduction – visual estimate                       |                                   |  |

### **Conclusions**

- In the planted courgette trials, coded product AHDB 9987 was crop safe when applied over the courgettes either at full rate alone or at ½ rate in a tank mix with Gamit and would provide additional control of weeds such as fat hen, cranesbill, and wild radish and increase control of groundsel and sow thistle.
- Timing the herbicide application within two days of planting while the thicker cotyledons were present was safer than application a few days later once the true leaves had emerged.
- All of the experimental herbicides applied over the crop caused a slight check to growth which set the crop back by a week – this would need to be considered within harvest schedules.
- Bonalan (benfluralin) was crop safe.
- In the inter-row trials, both planted and drilled, all treatments were crop safe, many caused a check to growth but this was deemed acceptable.

- The contact desiccants; Shark, AHDB 9897 and Finalsan caused scorch where the spray contacted the edge of the leaves falling in the row, but the effect was transient.
- In the drilled crop, where the inter-row herbicides were applied, five products gave equivalent or better reduction in the percentage weed cover when compared to the standard inter-row application of diquat. The treatments were Wing-P at either 2.0 or 4.0 L/ha, AHDB 9897 + Phase II, Shark and Finalsan + Activator 90 applied twice.

### **Take home message**

Authorisation of AHDB 9987, Shark, and AHDB 9897 would improve weed control in courgette crops. AHDB 9897 + Phase II and Shark would be particularly useful as alternatives for inter-row application after the loss of diquat. Finalsan gained an authorization in 2020, (EAMU 1609/20) and should improve weed control when applied twice as an inter-row application.

## Objectives

1. Trial 1: to compare a number of post-planting herbicides with the commercial standard (isoxaben + clomazone pre-emergence) for selectivity (crop safety) and efficacy in courgettes.
2. Trial 2: to compare a number of residual and contact herbicides applied as inter-row applications with the commercial standard (diquat) for selectivity (crop safety) and efficacy in courgettes.
3. Trial 3: to compare promising newer pre-emergence and post-emergence herbicide programmes for courgettes; applied as both incorporated, over-the-row and inter-row applications for selectivity (crop safety) and efficacy in courgettes.

## Trial conduct

UK regulatory guidelines were followed but EPPO guideline took precedence. The following EPPO guidelines were followed:

| Relevant EPPO guideline(s) |  | Variation from EPPO |
|----------------------------|--|---------------------|
| EPPO PP1/135(4)            | Phytotoxicity assessment   | None                |
| EPPO PP1/152(4)            | Guideline on design and analysis of efficacy evaluation trials                           | None                |
| EPPO PP1/225 (2)           | Minimum effective dose   | None                |
| EPPO PP1/181 (4)           | Conduct and reporting of efficacy evaluation trials including good experimental practice | None                |
| EPPO PP 1/214(3)           | Principles of acceptable efficacy  | None                |
| EPPO PP 1/224(2)           | Principles of efficacy evaluation for minor uses   | None                |

| 25/07/2018      | 55                      |                          | efficacy, phytotox                   | Percentage of weeds killed – whole plot score<br>Phytotox (scale 0-10, 0 = Dead)                              |

\* DA – days after application

## Statistical analysis

All trials had randomised block designs, each with treatments replicated three times.

All data were analysed by ANOVA using Genstat 18.4 by Chris Dyer and Emily Lawrence at RSK ADAS.

As each trial site had an uneven distribution of weeds – which is not unexpected in field situations – there was a need to transform weed cover data prior to analysis. To determine treatment efficacy, an angular transformation was performed then the back transformed means presented, from which the % reduction in weeds was calculated using Abbott’s formula. This was only completed for Trials 1-3, as in trials 4-5 weed control was assessed by a visual estimate of percentage weed kill.

## **Results – Trial 1 (planted crop, over the row applications) and Trial 2 (planted crop, inter-row applications)**

### ***Phytotoxicity***

The results of phytotoxicity assessments from three dates are presented in Table 1 and **Figure 1** for the over the row trial, and in Table 2 and Figure 2 for the inter-row trial. These were scored on a scale from 0 to 10, with 0 being ‘dead’, and 10 being ‘no effect’. Plots deemed to have a commercially acceptable level of damage were scored 8 or above.

Phytotoxicity was recorded using the following scale:

| <b>Crop tolerance score</b> | <b>Equivalent to crop damage (% phytotoxicity)</b> |
|-----------------------------|--|
| 0                           | complete crop kill 100%                            |
| 1                           | 80-95% damage                                      |
| 2                           | 70-80%   |
| 3                           | 60-70%   |
| 4                           | 50-60%   |
| 5                           | 40-50%   |
| 6                           | 25-40%   |
| 7                           | 15-25%   |
| 8*                          | 10-15%   |
| 9                           | 5-10%  |
| 10                          | no damage  |

\* 8 = acceptable damage, i.e. damage unlikely to reduce yield, and acceptable to the farmer.

**Trial 1** – With the exception of Flexidor + Gamit 36 CS applied the day after planting, all treatments applied within a week of planting had a significant effect on the crop which persisted for up to a month after planting. This was exhibited mainly as a check to growth with the crop remaining smaller than the untreated controls, or as scorch where Flexidor + Gamit 36 CS was applied over the crop at five days after planting. AHDB 9918 caused scorch and stunting when applied five days after planting, but only stunting when applied a day after planting.

At seven weeks after planting, plots where treatments were applied the day after planting, and AHDB 9987 at half rate in a tank mix with Gamit 36 CS applied at the later timing had recovered to a near acceptable level, or an acceptable level of damage.

All treatments had slightly less effect on the crop when the herbicides were applied the day after planting compared to when they were applied at five days after planting. All give a check to growth, which should be considered with scheduling and speed of growth at application.

AHDB 9985 was tested at two later application timings and had very little effect on the courgette plants when applied at four weeks after planting, compared to when it was applied two weeks later at flowering. But, even when AHDB 9985 was applied at flowering the effect on the crop was a stunt which was recorded as only just under the acceptable score.

**Table 1.** Mean phytotoxicity scores at three dates throughout the Trial 1 assessment period (0 to 10; 0 = complete crop death, 10 = no damage). Scores  $\geq 8$  deemed commercially acceptable damage, those  $< 8$  (unacceptable damage) are highlighted in bold. Letters denote spray timing: B = 1 day after planting, C = 5 days after planting, D = 4 weeks after planting, E = flowering.

**Figure 1.** Mean phytotoxicity (0-10) at two, four and seven weeks after Timing B treatment application to Trial 1. Scores of 8 or above deemed acceptable damage (as indicated by red line). Letters denote spray timing.

**Trial 2 (inter-row)** – A number of the treatments caused a check to speed of growth even when applied inter-row, but in many cases, it was only just under an acceptable score. At the end of the assessment period (early fruit) those treatments which did not have a score below eight were; the commercial standard diquat, AHDB 9995 in a tank mix with Flexidor and Gamit 36 CS, AHDB 9998, AHDB 9825 (alone and in a tank mix with Wing-P), and AHDB 9897 + Phase II.

Crop effects seen were a check to speed of growth and crop variability, and a little transient scorch or yellowing from the contact desiccants Shark, AHDB 9897 and Finalsan. The check to growth would likely be acceptable if enough weed control is gained as this can be factored into schedules, for example this approach is used where Wing-P is now included in commercial programmes.

**Table 2.** Mean phytotoxicity scores at three dates throughout the Trial 2 assessment period (0 to 10; 0 = complete crop death, 10 = no damage). Scores  $\geq 8$  deemed commercially acceptable damage, those  $< 8$  (unacceptable damage) are highlighted in bold. Letters denote spray timing: B = 1 day after planting, D = 4 weeks after planting, E = flowering.

| Treatment                              | Timing  | Mean crop damage scores |                       |                         |

### Weed control – mean percentage weed cover

#### Trial 1

The results for the mean percentage weed cover per treatment are presented in Table 3 and Figure 3. The percent reduction in weed cover compared to the untreated control was calculated from these figures (using Abbott's formula), and results for each treatment are listed in Table 4.

Weed levels were low, and there were no significant differences in weed control.

**Table 3.** Mean percentage weed cover values for Trial 1 (transformed). Letters denote spray timing: B = 1 day after planting, C = 5 days after planting, D = 4 weeks after planting, E = flowering.

## Results – Trial 3 (benfluralin screen)

### *Phytotoxicity*

The results of phytotoxicity assessments from three dates are presented in Table 7 and Figure 5.

There were no significant differences between scores, but where any herbicides were applied over the crop post-planting, this caused the crop damage score to drop below an acceptable level by causing a check to crop growth which set the crop back a week. However, by the final assessment at early fruiting all plots treated with all except AHDB 9918 had recovered to a near acceptable standard. Bonalan (benfluralin) did not cause any unacceptable damage to the courgettes, or any perceptible reduction in the speed of growth.

**Table 7.** Mean phytotoxicity scores at three dates throughout the Trial 3 assessment period (0 to 10; 0 = complete crop death, 10 = no damage). Scores  $\geq 8$  deemed commercially acceptable damage, those  $< 8$  (unacceptable damage) are highlighted in bold. Letters denote spray timing: A = pre-planting and incorporated, and B = 5 days after planting.

\* inter-row application

**Figure 5.** Mean phytotoxicity (0-10) at five, seven and nine weeks after Timing A treatment application to Trial 3. Scores of 8 or above deemed acceptable damage (as indicated by red line).

#### **Weed control – mean percentage weed cover**

The results for the mean percentage weed cover per treatment are presented in Table 8 and Figure 6. The percent reduction in weed cover compared to the untreated control was calculated from these figures (using Abbott's formula), and results for each treatment are listed in Table 9.

There were weakly significant differences between treatments, and the addition of either AHDB 9987 or AHDB 9918 increased the weed control compared to just Bonalan alone for up to four weeks after application.

**Table 8.** Mean percentage weed cover values for Trial 3 (transformed). Letters denote spray timing: A = pre-planting and incorporated, and B = 5 days after planting.

## Results – Trial 4 (drilled crop, over the row applications)

### *Phytotoxicity*

The results of phytotoxicity assessments from three dates are presented in Table 10 and Figure 7.

All of the pre-emergence herbicide treatments were safe to use in drilled courgettes in this trial with only a little yellowing caused where AHDB 9987 + Gamit was applied. This occurred at two months after application and would be likely to be caused by the Gamit moving into the rooting zone after a rain event. However, the damage was only just under acceptable. Wing-P 2.0 L/ha was damaging and caused crop death in the drilled pumpkin trial (see separate report) so care still needs to be taken when using this product in a drilled cucurbit crop. The soil type at this trial site was a clay loam, and demonstrates the influence that soil type can have on crop safety with the product being safe at this site, but causing crop death on the pumpkin trial site with a sandy soil. However, at this site it still caused a slight but acceptable check to the speed of growth of the courgettes.

None of the post-emergence applications caused any unacceptable crop effects with the exception of AHDB 9994, which caused a moderate check to the growth of the crop, scorch and yellow spotting. In the inter-row application of diquat there was drift which caused crop death and confounded assessment of the effects of AHDB 9985, although yellowing was observed after application of AHDB 9985 when applied at flowering. This was not seen at the Trial 1 site, but conditions at application at Trial 4 were duller and therefore there would be more risk of damage if the leaves were not as well waxed up at application.

**Table 10.** Mean phytotoxicity scores at three dates throughout the Trial 4 assessment period (0 to 10; 0 = complete crop death, 10 = no damage). Scores  $\geq 8$  deemed commercially acceptable damage, those  $< 8$  (unacceptable damage) are highlighted in **bold**.

\* Statistically different to untreated

**Figure 7.** Mean phytotoxicity (0-10) at four, six and eight weeks after drilling and the pre-emergence treatment application to Trial 4. Scores of 8 or above deemed acceptable damage (as indicated by red line). Post-emergence applied at four weeks after drilling

**Weed control – mean percentage weed kill**

The results for the mean percentage of weed reduction per treatment are presented in Table 11 and Figure 8. The data was collected in this way as the percentage of cover in the untreated was at 100% at the first assessment. Therefore, the data was not transformed under advice from our statistician.

**Table 11.** Mean percentage weed kill (weed reduction) values for Trial 4 showing the original data and 'percent kill' meaning the percentage of weeds killed by the herbicide programmes. For example, 100%= 100% weeds killed with zero weeds present. Letters denote spray timing: F = pre-emergence, G = at 3 true leaves, H = one month after drilling (flowering)

\*Untreated control; treatments 1 and 2

Four treatments reduced the percentage overall weed level greater than 25% by visual estimate at the final assessment. These were AHDB 9995 + Gamit 36CS, Wing-P 2.0 L/ha and Wing P 2.0 L/ha + AHDB 9998 applied pre-emergence, as well as AHDB 9994 applied post-emergence. (Figure 10 and Table 11). Only the pre-emergence treatments were safe to the courgettes.

Due to the manner the in which data was collected as a visual estimate of percentage weed kill rather than percentage weed cover, we were unable to carry out statistical analyses.

**Figure 8.** Total mean percentage weeds killed at the Timing H (T3) and two weeks after Timing H treatment application to Trial 4. *Note the maximum value of 80% on the y axis.*

## Results - Trial 5 (drilled crop, inter-row applications)

### Phytotoxicity

The results of phytotoxicity assessments from three dates are presented in Table 12 and Figure 9. All treatments were crop safe with none causing unacceptable damage to the courgettes (Table 15).

**Table 12.** Mean phytotoxicity scores at three dates throughout the Trial 5 assessment period (0 to 10; 0 = complete crop death, 10 = no damage). Scores  $\geq 8$  deemed commercially acceptable damage, those  $< 8$  (unacceptable damage) are highlighted in **bold**. Letters denote spray timing: F = pre-emergence, G = at 3 true leaves, H = one month after drilling (flowering)

**Figure 9.** Mean phytotoxicity (0-10) at four, six and eight weeks after Timing F treatment application to Trial 5. Scores of 8 or above deemed acceptable damage (as indicated by red line).

#### **Weed control – mean percentage weed kill**

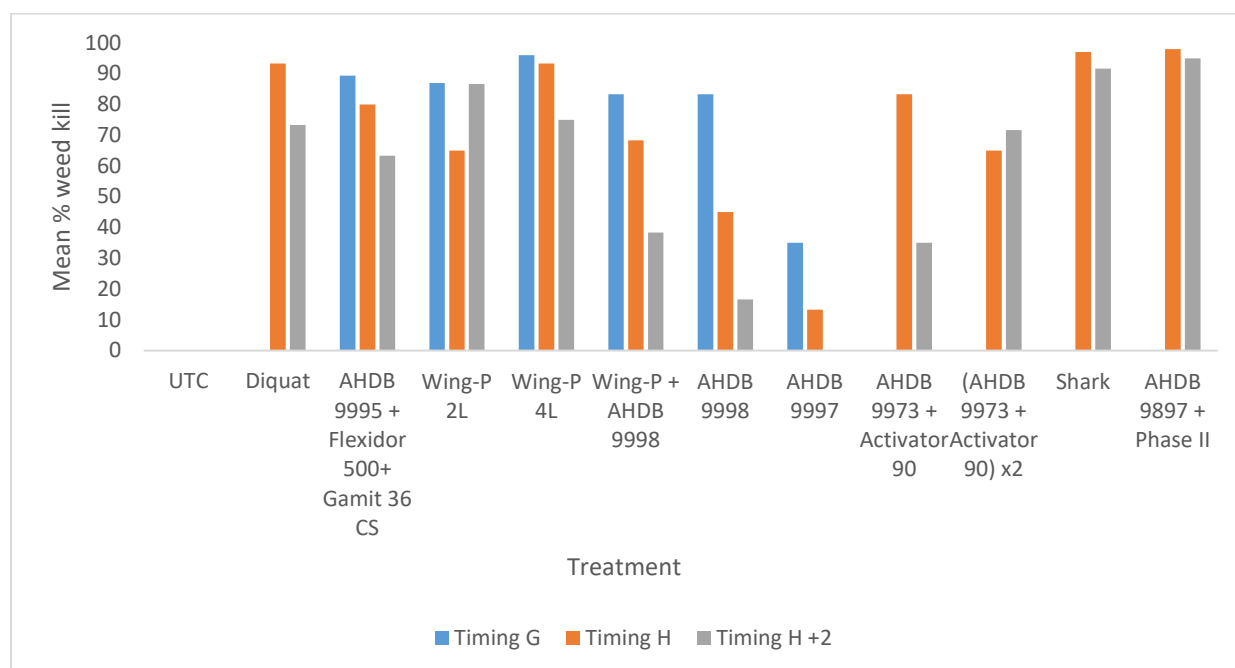

Five products gave equivalent or better reduction in the percentage weed cover when compared to the standard inter-row application of diquat. The treatments were Wing-P at either 2.0 or 4.0 L/ha, AHDB 9897 + Phase II, Shark and Finalsan + Activator 90 applied twice.

AHDB 9897 + Phase II was the most effective treatment reducing the weed level by the highest percentage, (Table 13 and Figure 10). Finalsan + Activator 90 was much more effective as a double application when compared to the single application, increasing weed reduction from 35% to 71.7%.

**Table 13.** Mean percentage weed kill (weed reduction) values for Trial 5 showing the original data and 'percent kill' meaning the percentage of weeds killed by the herbicide programmes. For example, 100%= 100% weeds killed with zero weeds present.

| Treatment                                   | Application Timing | Mean % weed reduction – visual estimate                        |                                   |  |

## Discussion

### Site 1- transplanted into plastic mulch

There were low weed levels at the trial site, and therefore significant differences in efficacy could not be determined for trials 1 and 2. However, useful differences in crop safety were observed through all trials at the site.

### Trial 1 (over-row)

With the exception of Flexidor + Gamit 36 CS applied the day after planting, all treatments applied within a week of planting had a significant effect on the crop which persisted for up to a month after planting. This was exhibited mainly as a check to growth with the crop remaining smaller than the untreated controls, or as scorch where Flexidor + Gamit 36 CS was applied over the crop at five days after planting. AHDB 9918 caused scorch and stunting when applied five days after planting, but only stunting when applied a day after planting.

At seven weeks after planting, plots where treatments were applied the day after planting, and AHDB 9987 at half rate in a tank mix with Gamit 36 CS applied at the later timing had recovered to a near acceptable level, or an acceptable level of damage.

All treatments had slightly less effect on the crop when the herbicides were applied the day after planting compared to when they were applied at five days after planting. All give a check to growth, which should be considered with scheduling and speed of growth at application.

AHDB 9985 was tested at two later application timings and had very little effect on the courgette plants when applied at four weeks after planting, compared to when it was applied two weeks later at flowering. But, even when AHDB 9985 was applied at flowering the effect on the crop was a stunt which was recorded as only just under the acceptable score. In Trial 5 a bleaching was observed, which was likely due to weather conditions at application – which was dull, and therefore the courgette leaves may not have been 'waxed up'.

### Trial 2 (inter-row)

There were low weed levels at the trial site, and therefore significant differences in efficacy could not be determined. However, useful differences in crop safety were observed.

A number of the treatments caused a check to speed of growth even when applied inter-row, but in many cases it was only just under an acceptable score with no crop loss. At the end of the assessment period (early fruit) those treatments which did not have a score below eight were; the commercial standard diquat, AHDB 9995 in a tank mix with Flexidor and Gamit 36 CS, AHDB 9998, AHDB 9825 (alone and in a tank mix with Wing-P), and AHDB 9897 + Phase II.

Crop effects seen were a check to speed of growth and crop variability, and a little transient scorch or yellowing from the contact desiccants Shark, AHDB 9897 and Finalsan. The check to growth would likely be acceptable if enough weed control is gained as this can be factored into schedules, for example this approach is used where Wing-P is now included in commercial programmes.

### Trial 3 (benfluralin)

Crop safety: There were no significant differences between scores, but where any herbicides were applied over the crop post-planting, this caused the crop damage score to drop below an acceptable level by causing a check to crop growth which set the crop back a week. However, by the final assessment at early fruiting all plots treated with all except AHDB 9918 had recovered to a near acceptable standard. Bonalan (benfluralin) did not cause any unacceptable damage to the courgettes, or any perceptible reduction in the speed of growth.

Weed cover: There were weakly significant differences between treatments. The addition of either AHDB 9987 or AHDB 9918 increased the weed control compared to just Bonalan alone for up to four weeks after application. However, AHDB 9918 caused the greatest phytotoxic effects.

## Site 2- drilled crop with no plastic mulch

### Trial 4 (over-row)

Three pre-emergence treatments combined crop safety with a reduction of the percentage overall weed level greater than 25% by visual estimate at the final assessment. These were AHDB 9995 + Gamit 36CS, Wing-P 2.0 L/ha and Wing P 2.0 L/ha + AHDB 9998.

All of the pre-emergence herbicide treatments were safe to use in drilled courgettes in this trial with only a little yellowing caused where AHDB 9987 + Gamit was applied. This occurred at two months after application and would be likely to be caused by the Gamit moving into the rooting zone after a rain event. However, the damage was only just under acceptable. Wing-P 2.0 L/ha was damaging and caused crop death in the drilled pumpkin trial (see separate report SP13. 2018) so care still needs to be taken when using this product in a drilled cucurbit crop. The soil type at this trial site was a clay loam, and demonstrates the influence that soil type can have on crop safety with the product being safe at this site, but causing crop death on the pumpkin trial site with a sandy soil. However, at this site it still caused a slight but acceptable check to the speed of growth of the courgettes.

None of the post-emergence applications caused any unacceptable crop effects with the exception of AHDB 9994, which caused a moderate check to the growth of the crop, scorch and yellow spotting. In the inter-row application of diquat there was drift which caused crop death and confounded assessment of the effects of AHDB 9985, although yellowing was observed after application of AHDB 9985 when applied at flowering. This was not seen at the Trial 1 site, but conditions at application at Trial 4 were duller and therefore there would be more risk of damage if the leaves were not as well waxed up at application.

### Trial 5 (inter-row)

Five products gave equivalent or better reduction in the percentage weed cover when compared to the standard inter-row application of diquat. The treatments were Wing-P at either 2.0 or 4.0 L/ha, AHDB 9897 + Phase II, Shark and Finalsan + Activator 90 applied twice.

AHDB 9897 + Phase II was the most effective treatment reducing the weed level by the highest percentage. Finalsan + Activator 90 was much more effective as a double application when compared to the single application, increasing weed reduction from 35% to 71.7%. All treatment programmes were crop safe.

## Conclusions

- In the planted courgette trials, coded product AHDB 9987 was crop safe when applied over the courgettes either at full rate alone or at ½ rate in a tank mix with Gamit and would provide additional control of weeds such as fat hen, cranesbill, and wild radish and increase control of groundsel and sow thistle.
- Timing the herbicide application within two days of planting while the thicker cotyledons were present was safer than application a few days later once the true leaves had emerged.
- All of the experimental herbicides applied over the crop caused a slight check to growth which set the crop back by a week – this would need to be considered within harvest schedules.
- Bonalan (benfluralin) was crop safe.
- In the inter-row trials, both planted and drilled, all treatments were crop safe, many caused a check to growth but this was deemed acceptable.
- The contact desiccants; Shark, AHDB 9897 and Finalsan caused scorch where the spray contacted the edge of the leaves falling in the row, but the effect was transient.
- In the drilled crop, where the inter-row herbicides were applied, five products gave equivalent or better reduction in the percentage weed cover when compared to the standard inter-row application of diquat. The treatments were Wing-P at either 2.0 or 4.0 L/ha, AHDB 9897 + Phase II, Shark and Finalsan + Activator 90 applied twice.

## **Acknowledgements**

AHDB for funding the work, and also the crop protection companies for their financial contributions as well as providing samples for the trials. Thanks should also be given to the growers who provided sites and crops for the trials as well as technical input, particularly Jim Smith and Neil Cairns of Barfoots, and W.R Haines
