

**Project title:** Pests, Plants and Parasitoids: how does climatic variability affect tritrophic interactions in apple orchards?

**Project number:** CTP\_FCR\_2017\_5

**Project leader:** Dr.Jake Bishop, University of Reading  
Dr. Robbie Girling, University of Reading  
Dr.Glen Powell, NIAB EMR

**Report:** Annual report, October 2019

**Previous report:** NA

**Key staff:** Stuart Edwards

**Location of project:** University of Reading

**Industry Representative:** National Association of Cider Makers  
Worldwide Fruit Ltd

**Date project commenced:** October 1<sup>st</sup> 2017

# **GROWER SUMMARY**

## **Headline**

Climate change threatens species interactions in economically important crops leading to potential pest outbreaks.

## **Background**

Our current understanding is that species are likely to respond to temperature changes at different rates. This has implications for the control of aphid pests of apple in the future. For instance, aphids may be able to reproduce faster than their natural enemies in warmer conditions and escape control by natural means. The effectiveness of biological control may also change making them more or less efficient for pest control in the future. Understanding these changes will be crucial for pest control under future climates.

## **Summary**

Ever tightening restrictions of pesticide application in conventional production combined with an increasing demand for organic produce has increased the necessity of understanding the intricacies of pest control under predicted future climate scenarios. This project aims to quantify and model the responses of two apple pests (Woolly Apple Aphid and Green Apple Aphid) and their interactions in both plant and biological control in an attempt to influence future Integrated Pest Management (IPM) programmes.

## **Financial Benefits**

Due to the constraints of legislation and the potential for financial deficit through damaged crop yields, understanding the effects of climatic variability on pest-parasitoid interactions is key to all crop producing practices. Understanding trophic interactions in future climate scenarios will inform future IPM thus ensuring an acceptable level of pest control whilst potentially saving money by not applying unnecessary treatments. For example, should the ratio of pest to parasitoid exist at a level controllable by a parasitoid then it makes sense not to spray pesticides which will risk damaging the biological control population, such damage to the population risks a rebound behaviour in the pest species.

## **Action Points**

Whilst there are no grower action points stemming directly from this project at such an early stage. Early indications from a literature review suggest that supporting communities of natural enemies via increased habitat complexity and through provision of additional resources such as nectar will be crucial in ensuring optimal pest regulation by natural enemies in future climate scenarios.
